|        | -    | estions in space provided below questions. Use additional paper if necessary but make sure your every sheet.                                                                                                                                                                                                                                                          |       |
| Qu. 1  | Ans  | swer each of the following briefly:                                                                                                                                                                                                                                                                                                                                   | l /60 |
| (a)    | be d | spose 50% of a computation execution must be executed on a single processor but the remainder callivided into ten parallel parts of equal duration each of which can be executed by a separate cessor at the same time. What is the maximum speed up if you have four processors? Clearly explanation for simply putting down a numerical answer with an explanation. |       |
|        |      |                                                                                                                                                                                                                                                                                                                                                                       |       |
| (b)    | Why  | y are critical sections not used in MPI programs?                                                                                                                                                                                                                                                                                                                     | 2     |
| (c)    | In A | Assignment 1, what was the command "diff" used for?                                                                                                                                                                                                                                                                                                                   | 2     |

(d) In MPI, what is the term "rank" used for?

2

2

```
(e) What does the MPI code below do?
```

```
int main (int argc, char *argv[]) {
      int token, NP, myrank;
      MPI_Status status;
      MPI_Init (&argc, &argv);
      MPI_Comm_size(MPI_COMM_WORLD, &NP);
      MPI_Comm_rank(MPI_COMM_WORLD, &myrank);
      if (myrank != 0) {
            MPI_Recv(&token, 1, MPI_INT, myrank - 1, 0, MPI_COMM_WORLD, &status);
      } else {
            token = -1;
      token += 2;
      MPI_Send(&token, 1, MPI_INT, (myrank + 1) % NP, 0, MPI_COMM_WORLD);
      if (myrank == 0) {
            MPI Recv(&token, 1, MPI INT, NP - 1, 0, MPI COMM WORLD, &status);
      MPI Finalize();
}
```

(f) What is meant by a blocking MPI routine?

|     | The MPI collective routines are said to have the same semantics as using point-point MPI_send() and ecv() routines separately in respect to when they return. If so, when does the MPI_Gather() routine? Explain fully. | 2 |

| That is the parallel time complexity with $P$ processors where each processor handles $N/P$ numbers in the ompare and exchange operation? | 2 |

| (r) | Which is CUDA? |  | 2 |
|-----|----------------|--|---|
|     |                |  |   |

(s) What is nvcc?

(t) What is meant by flattening an array in GPU programming? Why is it used?

Qu. 2 Write a MPI program that implements a workpool consisting of a master process and 5 slave processes. The master sends a task consisting of two random integers to be added together to each slave. The slaves execute the task by adding the two integers and returns the result to the master. The master then sends another task to the slave, again consisting of two random integers to be added together. This continues until 100 tasks are completed.

Provide very clear explanation of how the program works, and comments in your code. If I do not understand the code, I will assume it is incorrect.

Qu 3 Given a sequence of letters consisting of 10,000 groups of 4 characters where each character can be A, C, G or T, write a CUDA program to find it how many groups consist of the sequence GCAT.

The number of threads in a block and number of blocks in the grid are to be given as #define constants, *T* and *B* respectively.

Some CUDA predefined variables:

The thread ID within a block in the x direction is given by threadIdx.x The block ID in the x direction is given by blockIdx.x The number of bocks in the x direction is given by blockDim.x

Provide very clear explanation of how the program works, and comments in your code. If I do not understand the code, I will assume it is incorrect.
